Electrochemical Power Systems

Battery Intelligence: Diagnosis and Prognosis

OBJECTIVE AND SIGNIFICANCE: This project aims at the development of approaches, tools, and protocols, to improve batteries diagnosis and prognosis via non-invasive in-operando techniques.

BACKGROUND: Battery diagnosis and prognosis is a difficult task. Lithium-ion batteries (LiB) are much more complex than traditional batteries and their degradation is path dependent as different usages (current, temperature, SOC range, SOC window..., etc.) will lead to different type of degradation. In addition, since large battery packs are composed of thousands of cells, the use of complex models or a multitude of sensors for each cell is precluded.

Traditionally, battery diagnosis is handled via two opposite approaches. The academic route aims for maximum accuracy and achieves it by inputting a lot of resources. The second route – the one usually used on deployed systems – uses as little resources as possible and must not be destructive. As a result, it is ineffective in predicting the true state of health.

This assessment of state of the art led HNEI to define and develop a third industry-compatible intermediate route to reach an accurate diagnosis with cost-effective and non-destructive methods, using only sensors already available in battery packs while requiring limiting computing power.

HNEI developed a mechanistic modeling framework where a battery digital twin is built from individual electrode data and where the battery degradation is

emulated by the scaling or the translation of one electrode versus the other. Using this framework, the voltage variations associated with the degradation mechanisms can be predicted.

Machine learning and artificial intelligence are also starting to play a crucial role to diagnose and prognose batteries. However, their accuracy is limited by the little to no training data available to validate algorithms. To solve this issue, HNEI applied the mechanistic modeling approach to develop the first synthetic training datasets using computer-generated voltage curves. Research conducted for this project is completed in the [PakaLi Battery Laboratory](#).

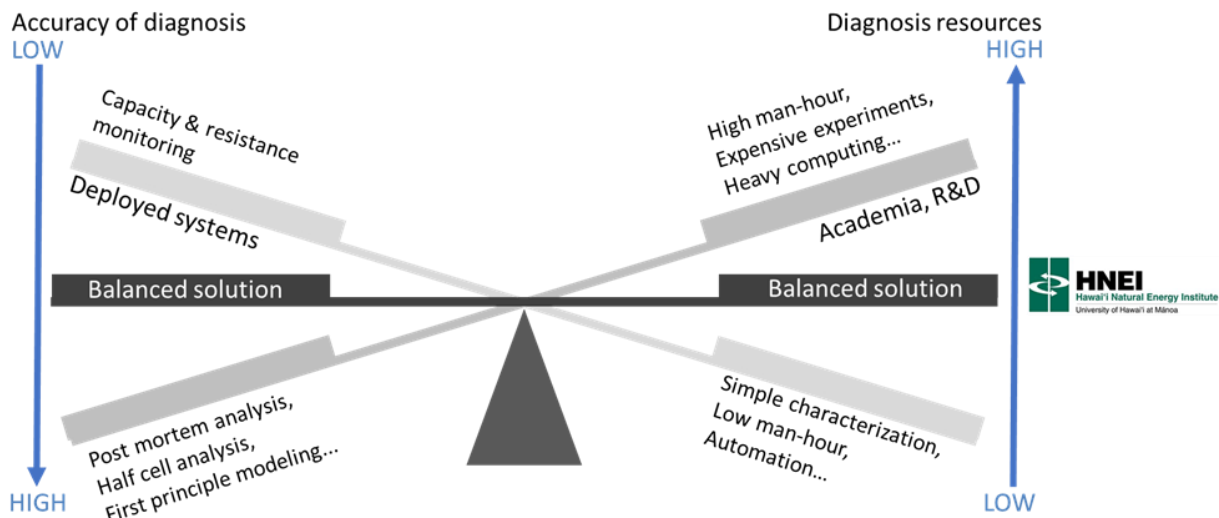

PROJECT STATUS/RESULTS: This project is currently ongoing with three industrial collaborations on different aspects of the problem. A full suite of software and models were developed. The main model has been licensed by more than 65 organizations worldwide.

This work led to 36 publications, including the ones listed on the following page and one patent.

Funding Source: Office of Naval Research; SAFT (France); Element Energy; ACCURE (Germany)
